

r_P vs r_B by OOS quantile — Roman Model (Scaled) vs SP500
Blue = benchmark worst days | Orange = benchmark best days

Interpretation: the beta (β) annotated on each regression line measures the sensitivity of the portfolio return to the benchmark in that region. $\beta < 1$ on the worst days indicates downside protection (the portfolio loses proportionally less). $\beta > 1$ on the best days indicates upside capture (the portfolio gains proportionally more). The portfolio is compared against the sector Synthetic Benchmark — its optimisation benchmark.
